ABSTRACT: Field redefinitions occur in string compactifications at the one loop level. We review arguments for why such redefinitions occur and study their effect on moduli stabilisation and supersymmetry breaking in the LARGE volume scenario. For small moduli, although the effect of such redefinitions can be larger than that of the α' corrections in both the Kähler and scalar potentials, they do not alter the structure of the scalar potential. For the less well motivated case of large moduli, the redefinitions can dominate all other terms in the scalar potential. We also study the effect of redefinitions on the structure of supersymmetry breaking and soft terms.

1. Introduction

In the study of string compactifications moduli stabilisation plays an essential role in attempts to generate a realistic phenomenology. Moduli stabilisation is necessary to give masses to the light moduli that would otherwise give fifth forces, and is also necessary to avoid runaway and decompactification. Furthermore the moduli potential plays a crucial role in setting both the scale of supersymmetry breaking and the value of the gravitino mass, and so represents a necessary ingredient of any ultraviolet-consistent model of supersymmetry breaking.

One set of promising models of moduli stabilisation are the LARGE volume models originally developed in [1, 2]. The main attractive feature of these is that they both stabilise all moduli and dynamically break supersymmetry at exponentially small scales. In this way they address one of the main obstacles to stringy phenomenology and also one of the outstanding issues of BSM physics, namely how to generate hierarchies.

An important role in the LARGE volume models is played by corrections to the Kähler potential [3]. The minimum of the scalar potential comes from competition between a perturbative α' correction to the Kähler potential and non-perturbative corrections to the superpotential. While the form of the superpotential is restricted by non-renormalisation theorems, the Kähler potential is not constrained. To analyse the robustness of the LARGE

volume scenario it is therefore important to check the effect of all other possible corrections to the Kähler potential.

These corrections fall into several forms. The most obvious kind are those of other α' corrections. The LARGE volume models involve the correction to the Kähler potential induced by the $\mathcal{R}^4$ term present at $\mathcal{O}(\alpha'^3)$ in the 10d IIB action. There are many other additional terms (for example flux terms such as $G^2\mathcal{R}^4$). Such α' terms were considered in [2]. At large volume such terms are all subleading compared to the $\mathcal{R}^4$ term, essentially because the $\mathcal{R}^4$ term is suppressed by six powers of length, while flux terms are suppressed by higher powers (as flux is quantised on multi-dimensional cycles).

Another form of correction are those induced by string loop corrections to the Kähler potential. For some toroidal models these have been calculated in [4, 5] (also see [6]). For more general models the Coleman-Weinberg potential has been used to constrain the form and magnitude of loop corrections [7, 8, 9]. One interesting property of such loop corrections is that they do in general induce corrections in the Kähler potential that dominate at large volume over the α'^3 corrections. However, due to an extended no-scale structure such loop corrections in fact cancel at leading order in the scalar potential [7], remaining subdominant to the α'^3 corrections. Other studies of the robustness of the LARGE volume scenario include [10, 11, 12].

This paper will study another form of possible correction that does not seem to fall neatly into either of the classes above. This refers to the effect of field redefinitions that can occur at the loop level. In such redefinitions the relationship between the holomorphic moduli and the physical cycle volumes is modified at 1-loop, such that the holomorphic moduli no longer correspond directly to cycle sizes. As the Kähler potential involves the physical volume this should lead to a correction to the Kähler potential as the expression for the physical volumes in terms of the moduli changes.

The existence of such redefinitions has been established for various orbifold models where exact string computations are possible. It is certainly plausible that such redefinitions survive beyond the orbifold limit in which they were computed. We shall assume this applies, and then study the effect of redefinitions on moduli stabilisation and the computation of soft terms. The structure of the paper is as follows. In section 2 we review the LARGE volume scenario and the particular model we study, defined by a hypersurface in $\mathbb{P}^4_{[1,1,1,6,9]}$. In section 3 we review how field redefinitions occur in orbifolds and give a new argument for their occurrence in the geometric regime. In section 4 we study the effect of such redefinitions on moduli stabilisation, and in section 5 we extend this study to the effects on soft supersymmetry breaking. In section 6 we conclude.

2. The LARGE Volume Scenario

We start by reviewing the basic features of the LARGE Volume Scenario for Type IIB orientifolds, proposed in [1]. Neglecting gauge interactions, a 4-dimensional supergravity model is specified entirely by the Kähler potential and the superpotential. To leading order

in g_s and α' the Kähler potential is given by [13]

$$\hat{K} = -2 \ln[\mathcal{V}] - \ln \left[-i \int_{\mathcal{M}} \Omega \wedge \bar{\Omega} \right] - \ln[-i(\tau - \bar{\tau})] \quad (2.1)$$

where $\mathcal{V}$ is the volume of $\mathcal{M}$ measured in the Einstein frame ($g_E = e^{-\phi/2} g_s$) in units of the string length $l_s = 2\pi\sqrt{\alpha'}$. The volume is given by

$$\mathcal{V} = \frac{1}{6} \int_{\mathcal{M}} J \wedge J \wedge J = \frac{1}{6} k_{ijk} t^i t^j t^k, \quad (2.2)$$

where J is the Kähler form of $\mathcal{M}$, k_{ijk} are triple intersection numbers and t^i are two-cycle volumes. The fields appearing in the 4D effective theory are the complexified Kähler moduli $T_i \equiv -i\rho_i = \tau_i + ib_i$ where b_i is the axion and the τ_i are the Einstein frame four-cycle volumes, given by:

$$\tau_i = \frac{\partial \mathcal{V}}{\partial t^i} = \frac{1}{2} k_{ijk} t^j t^k. \quad (2.3)$$

The tree level superpotential is given by [14, 15]

$$\hat{W} = \int_{\mathcal{M}} G_3 \wedge \Omega, \quad (2.4)$$

where Ω is the (3,0) form of the Calabi-Yau and $G_3 = F_3 - \tau H_3$. It is important to note that $\hat{W}$ is independent of the Kähler moduli.

The class of models defined by Eqs. (2.1) and (2.4) are examples of no-scale models. The $\mathcal{N} = 1$ supergravity scalar potential is

$$V = e^K (G^{i\bar{j}} D_i W D_{\bar{j}} \bar{W} - 3|W|^2). \quad (2.5)$$

Computing the scalar potential using the Kähler potential and the superpotential of Eqs. (2.1) and (2.4) one finds that Eq. (2.5) reduces to

$$V_{no-scale} = e^K (G^{a\bar{b}} D_a W D_{\bar{b}} \bar{W}), \quad (2.6)$$

where the sum runs over only the dilaton and the complex structure moduli. The Kähler moduli dependence in Eq. (2.6) appears just as an overall factor. $V_{no-scale}$ is positive definite and fixes the dilaton and complex structure moduli at a locus given by

$$D_a \hat{W} \equiv \partial_a \hat{W} + \hat{W} \partial_a K = 0. \quad (2.7)$$

The value of the superpotential when (2.7) is satisfied is denoted by W_0 .

The no-scale structure is a tree-level result and is broken by both α' and g_s effects. In [3] it was shown that the inclusion of $\mathcal{O}(\alpha'^3)$ terms in the Kähler potential leads to the breaking of the no-scale structure of the scalar potential:

$$\hat{K} = -2 \ln \left[\mathcal{V} + \frac{\xi (\frac{S+\bar{S}}{2})^{3/2}}{2} \right] - \ln \left[-i \int_{\mathcal{M}} \Omega \wedge \bar{\Omega} \right] - \ln[-i(\tau - \bar{\tau})], \quad (2.8)$$

where $\xi = -\frac{\zeta(3)\chi(\mathcal{M})}{2(2\pi)^3}$ with $\chi(\mathcal{M}) = h^{2,1} - h^{1,1}$. We focus on the case $\xi > 0$ which is equivalent to having more complex structure than Kähler moduli. The no-scale structure can also be broken by (non-perturbative) corrections to the superpotential [16], giving it the form

$$\hat{W} = \int_{\mathcal{M}} G_3 \wedge \Omega + \sum_i A_i e^{ia_i \rho_i}. \quad (2.9)$$

In [1] it was shown that the combination of these two effects can generate minima of the scalar potential at exponentially large volumes. To study these we first stabilise the dilaton and the complex-structure moduli by solving Eq. (2.7) and then regard their values as fixed (this approximation is justified *post hoc* by the large value of the stabilised volume, which gives minimal cross-coupling between these sectors).

The resulting theory is only dependent on the Kähler moduli and is specified by

$$\hat{K} = -2 \ln[\mathcal{V} + \frac{\xi}{2g_s^{3/2}}] + K_{cs}, \quad (2.10)$$

and

$$\hat{W} = W_0 + \sum_i A_i e^{-a_i T_i}. \quad (2.11)$$

The original discussion of the minima of the potential in Eq. (2.5) for a generic compactification manifold can be found in [1], establishing the existence of an AdS minimum at exponentially large volumes. Subsequent discussions extending this to more general manifolds can be found in [8]. For the purposes of this paper we will focus on the original model used in [1], namely a degree 18 hypersurface in $\mathbb{P}^4_{[1,1,1,6,9]}$. For reference we briefly review this case. In terms of the 4-cycles the volume of the manifold is given by

$$\mathcal{V} = \frac{1}{9\sqrt{2}}(\tau_b^{3/2} - \tau_s^{3/2}) \equiv \frac{1}{\lambda}(\tau_b^{3/2} - \tau_s^{3/2}). \quad (2.12)$$

Equations (2.10), (2.11) and (2.12) allow us to compute the scalar potential from Eq. (2.5) obtaining

$$V = \frac{8\lambda a^2 |A|^2}{3\mathcal{V}} e^{-2a\tau_s} \sqrt{\tau_s} - 4 \frac{|AW|}{\mathcal{V}^2} a\tau_s e^{-a\tau_s} + \frac{3}{4} \frac{|W|^2 \xi}{\mathcal{V}^3 g_s^{3/2}}. \quad (2.13)$$

We want to find the minimum of this potential and to study its properties. For that one must solve $\frac{\partial V}{\partial \tau_b} = \frac{\partial V}{\partial \tau_s} = 0$. The first condition yields

$$\frac{\partial V}{\partial \mathcal{V}} = 0 \Leftrightarrow \mathcal{V} = \frac{3|W|}{2\lambda a A} \sqrt{\tau_s} e^{a\tau_s} \left(1 \pm \sqrt{1 - \frac{3\lambda\xi}{8g_s^{3/2}\tau_s^{3/2}}} \right), \quad (2.14)$$

while the second

$$\frac{\partial V}{\partial \tau_s} = 0 \Leftrightarrow \left(\frac{1}{2} - 2a\tau_s \right) \left(1 \pm \sqrt{1 - \frac{3\lambda\xi}{8g_s^{3/2}\tau_s^{3/2}}} \right) = (1 - a\tau_s). \quad (2.15)$$

In the limit of large $a\tau_s$ Eq. (2.15) becomes

$$\tau_s^{3/2} \approx \frac{\lambda\xi}{g_s^{3/2}} \left(\frac{1}{2} + \frac{1}{4a\tau_s} + \mathcal{O}(a\tau_s)^{-2} \right). \quad (2.16)$$

Equation (2.16) gives an implicit solution for τ_s , one can get an explicit expression by solving it iteratively. The first iteration will be

$$\tau_s^{3/2} \approx \tilde{\tau}_s^{3/2} \left(1 + \frac{1}{2a\tilde{\tau}_s} \right), \quad (2.17)$$

where $\tilde{\tau}_s^{3/2} = \frac{\lambda\xi}{2g_s^{3/2}}$. We will use eq. (2.17) as our analytical expression for τ_s at the minimum, neglecting the small subleading $\mathcal{O}(a^{-2}\tau_s^{-2})$ corrections. We can also expand Eq. (2.14) in powers of $\frac{1}{a\tau_s}$ to find:

$$\mathcal{V} = \frac{3|W_0|}{4\lambda a|A|} \sqrt{\tau_s} e^{a\tau_s} \left(1 - \frac{3}{4a\tau_s} + \mathcal{O}(a^{-2}\tau_s^{-2}) \right). \quad (2.18)$$

3. 1-loop Kähler Moduli Redefinition

The purpose of this paper is to study the effects of field redefinitions on moduli stabilisation. It is a known feature of string compactifications that the definitions of moduli are altered at 1-loop level. Specifically, what is altered is the definition of the chiral superfields of the supergravity action in terms of the geometric quantities of the compactification.

The LARGE volume models involve a large overall volume together with smaller blow-up cycles. If such blow-up cycles were collapsed to a point, they would generate a singularity. Branes at singularities were recently studied in the context of threshold corrections in [17, 18]. It was found there that in various cases consistency with the effective supergravity - specifically the Kaplunovsky-Louis formula describing the effect of anomalous contributions to gauge coupling running - required that the modulus controlling the blow-up cycle had to be redefined at 1-loop level. For other examples of 1-loop redefinitions in the context of theories with D-branes, see [19, 20]. We emphasise that here we focus on the role of Kähler moduli in the redefinition; the dilaton and complex structure moduli will also appear, but as these are flux-stabilised redefinitions will be less important.

The redefinition did not occur in all cases (for example it occurred for D3 branes at orientifolded singularities, but not at orbifolded singularities). Where it did occur the redefinition took the form of a shift by a factor proportional to the logarithm of the overall volume of the CY:

$$\tau_{new} = \tau_{old} - \alpha \ln(\mathcal{V}), \quad (3.1)$$

where α is taken to be small. The physical cycle volume (which vanishes at the singularity) corresponds to τ_{old} . The holomorphic modulus τ_{new} is however non-zero at the singularity. We also note the types of cycles for which the redefinition occurs (blow-up cycles) are essentially the same as the blow-up moduli that play a crucial role in the LARGE volume construction.

While such orbifold calculations show that field redefinitions occur, they are restricted to the singular limit. Let us give another argument for why field redefinitions should take place, this time in the geometric regime. Consider an isolated collapsible cycle (e.g. a $\mathbb{P}^2$) taken to itself under an orientifold action, such that an O-plane wraps it and a stack of D-branes is on top of the O-planes giving a rigid $\mathcal{N} = 1$ SYM theory. This is the type of dynamics required on the small cycle in the LARGE volume scenario. Such a theory will undergo gaugino condensation and generate a non-perturbative superpotential. The classical tree-level gauge coupling is given by

$$\frac{4\pi}{g^2} = \tau, \quad (3.2)$$

where τ is the Einstein frame physical volume of the 4-cycle measured in units of the string length ($e^{-\phi}\text{Vol}_\Sigma/(2\pi\sqrt{\alpha'})^4$). The running gauge coupling is then given by

$$\frac{1}{g^2}(\mu) = \frac{\tau}{4\pi} + \frac{\beta}{16\pi^2} \ln \left(\frac{\Lambda_{UV}^2}{\mu^2} \right), \quad (3.3)$$

and so $\Lambda_{strong} = \Lambda_{UV} e^{-\frac{2\pi\tau}{\beta}}$. The condensing gauge group also generates a holomorphic superpotential

$$W = M_P^3 e^{-\frac{3}{\beta}(2\pi T)}. \quad (3.4)$$

Here T is the chiral superfield corresponding to the 4-cycle wrapped by the branes, given classically by $T = \tau + i \int_\Sigma C_4$, but as we will see this does not have to hold at loop level. The prefactor of M_P^3 in (3.4) is enforced by supergravity: M_P is the only dimensionful quantity present in 4d supergravity and so is the only quantity that can appear here. In particular, quantities such as the string scale $M_s = M_P/\sqrt{\mathcal{V}}$ cannot appear in (3.4) as they violate holomorphy.

However, the normalised superpotential should also be identified with the strong coupling scale:

$$e^{K/2}W = \langle \bar{\lambda}\lambda \rangle = \Lambda_{strong}^3. \quad (3.5)$$

Using $\mathcal{K} = -2 \ln \mathcal{V}$, we therefore obtain

$$\Lambda_{strong} = \Lambda_{UV} e^{-\frac{2\pi\tau}{\beta}} = \frac{M_P}{\mathcal{V}^{1/3}} e^{-\frac{2\pi\text{Re}(T)}{\beta}}. \quad (3.6)$$

In principal two possibilities can now occur. First, the UV scale from which couplings start running could be identified with $M_P/\mathcal{V}^{1/3}$. Indeed it is known [17, 18] that in various local models this is actually the scale from which couplings start running. However the detailed analysis of [17, 18] also reveals that the physics which effectively allows couplings to start running at a scale $M_W \equiv \frac{M_P}{\mathcal{V}^{1/3}} = RM_S$ corresponds to uncancelled RR tadpoles in the $\mathcal{N} = 2$ sector. These are tadpoles that are sourced locally but cancelled globally, and geometrically correspond to cycles which have homology representatives both locally and also in the bulk. However this does not apply here, where the cycle is purely local (it involves purely $\mathcal{N} = 1$ sectors; equivalently the cycle is dynamical in the local geometry).

This means we should identify Λ_{UV} with M_{string} , in which case consistency of equation (3.6) requires that

$$\text{Re}(T) = \tau + \frac{\beta}{2\pi} \ln \mathcal{V}^{1/6}. \quad (3.7)$$

As τ involves a factor of $e^{-\phi}$ from the Einstein frame volume, this represents a 1-loop redefinition of T which appears to be required for consistency with the framework of 4d supergravity.

Both the above arguments suggest moduli redefinitions may be occurring in geometries relevant to moduli stabilisation. We therefore think it is important to study the possible effects on moduli stabilisation. While the form of the superpotential must be unaltered (as before we focus on the dependence on the Kähler moduli; the dependence on the dilaton and complex structure moduli can change), the redefinitions can affect the Kähler potential. For the purpose of this paper we shall make a simple assumption as to the nature of these effects. The classical Kähler potential is given by $K = -2 \ln \mathcal{V}$, where $\mathcal{V}$ is the physical (Einstein frame) volume of the Calabi-Yau. In this paper we shall assume that the dependence on the physical volume remains the same, and that the change in the Kähler potential as a function of the moduli comes simply from re-expressing the volume in terms of the redefined moduli. This assumption could be verified by a 1-loop computation of the Kähler potential, which is however beyond the scope of this work.

We note both arguments relate to redefinitions of the small blow-up modulus. The motivation for redefinitions of the large modulus is weaker. Indeed in this case the explicit loop calculation of [4] does not show any evidence for it (as this was a toroidal computation, it should incorporate the behaviour of the overall volume modulus). For completeness we shall however also study redefinitions of this large modulus in the following section.

4. Moduli Stabilisation

In this section we investigate the consequences of 4-cycle volume redefinition in moduli stabilisation. We focus on the particular case of the $\mathbb{P}^4_{[1,1,1,6,9]}$ orientifold and study what happens to the position of the minimum, Eqs. (2.17) and (2.18), when we redefine τ_b and τ_s . We study these two cases separately.

4.1 Redefining τ_s

Redefining τ_s according to Eq. (3.1) we find that the Kähler potential for moduli fields becomes:

$$K = -2 \ln \left[\frac{1}{\lambda} (\tau_b^{3/2} - [\tau_s - \alpha \ln(\mathcal{V})]^{3/2}) + \frac{\xi}{2} \left(\frac{S + \bar{S}}{2} \right)^{3/2} \right] + K_{cs}. \quad (4.1)$$

We allow an arbitrary parameter α in the redefinition. Note the term proportional to α dominates at large volume over the term proportional to ξ . Computing the supergravity

scalar potential we find

$$V = \frac{1}{\tau_b^{9/2}} \left(-\frac{9}{2} |W_0|^2 \alpha \sqrt{\tau_s} \lambda^2 + \frac{3}{4} |W_0|^2 \frac{\lambda^3 \xi}{g_s^{3/2}} \right) + \frac{2}{3} \frac{a^2 |A|^2 \lambda^2 e^{-2a\tau_s}}{\tau_b^{3/2} \sqrt{\tau_s}} (4\tau_s - 2\alpha \ln(\mathcal{V})) - \frac{1}{\tau_b^3} a (\bar{A} e^{a\tau_s} W_0 + A e^{a\tau_s} \bar{W}_0) e^{-2a\tau_s} \lambda^2 (2\tau_s + 3\alpha - 2\alpha \ln(\mathcal{V})). \quad (4.2)$$

We have dropped terms that are subleading by powers of $\mathcal{V}$. This can be further simplified to:

$$V = \frac{3}{4} |W_0|^2 \frac{\xi \lambda^3}{g_s^{3/2}} \left(1 - \frac{6\alpha \sqrt{\tau_s}}{\xi \lambda} \right) \frac{1}{\tau_b^{9/2}} + \frac{8}{3} \frac{a^2 |A|^2 \lambda^2 e^{-2a\tau_s}}{\tau_b^{3/2}} \sqrt{\tau_s} \left(1 - \frac{\alpha}{2\tau_s} \ln(\mathcal{V}) \right) - \frac{\lambda^2}{\tau_b^3} 2a\tau_s (\bar{A} W_0 + A \bar{W}_0) e^{-a\tau_s} \left(1 - \frac{\alpha}{\tau_s} \ln(\mathcal{V}) \right), \quad (4.3)$$

by noting that at the minimum we expect $\ln \mathcal{V} = a\tau_s \gg 1$ and that the nonperturbative part of the superpotential is small compared to W_0 . One can rewrite Eq. (4.3) as

$$V = \Lambda \left(1 - \frac{6\alpha g_s^{3/2} \sqrt{\tau_s}}{\xi \lambda} \right) \frac{1}{\tau_b^{9/2}} + \Omega \frac{\sqrt{\tau_s} e^{-2a\tau_s}}{\tau_b^{3/2}} \left(1 - \frac{\alpha}{2\tau_s} \ln \mathcal{V} \right) - \Psi \frac{\tau_s e^{-a\tau_s}}{\tau_b^3} \left(1 - \frac{\alpha}{\tau_s} \ln \mathcal{V} \right). \quad (4.4)$$

by defining

$$\Lambda = \frac{3}{4} |W_0|^2 \lambda^3 \xi / g_s^{3/2}, \quad (4.5)$$

$$\Omega = \frac{8}{3} a^2 |A|^2 \lambda^2, \quad (4.6)$$

$$\Psi = 2a\lambda^2 (\bar{A} W_0 + \bar{W}_0 A). \quad (4.7)$$

At this point we again note that the contribution from the field redefinition is dominant over the α'^3 correction also in the scalar potential as well as the Kähler potential. This makes the study of this potential particularly interesting as the α'^3 correction played an important role in establishing the existence of the original LARGE volume minimum.

To find the minimum of the potential one must solve $\frac{\partial V}{\partial \tau_s} = \frac{\partial V}{\partial \tau_b} = 0$. Keeping in mind that we expect $\ln \mathcal{V} \approx a\tau_s \gg 1$, from the first condition we find that at the minimum

$$\tau_b^{3/2} = \frac{\Psi}{2\Omega} \sqrt{\tau_s} e^{a\tau_s} \left(1 - \frac{3}{4a\tau_s} - \frac{\alpha}{2\tau_s} \ln \mathcal{V} \right), \quad (4.8)$$

while the second condition yields:

$$\tau_s = \left(\frac{4\Lambda\Omega}{\Psi^2} \right)^{2/3} \left(1 + \frac{1}{3a\tau_s} + \alpha \left(\frac{\ln \mathcal{V}}{\tau_s} - \frac{4g_s^{3/2} \sqrt{\tau_s}}{\lambda \xi} \right) \right). \quad (4.9)$$

Using the definitions in Eqs. (4.5)-(4.7) we may rewrite these equations as:

$$\tau_s = \tilde{\tau}_s \left(1 + \frac{1}{3a\tau_s} + \alpha \left(\frac{\ln \mathcal{V}}{\tau_s} - \frac{2}{\tilde{\tau}_s} \right) \right), \quad (4.10)$$

$$\tau_b = \tilde{\tau}_b \left(1 - \frac{1}{2a\tau_s} - \frac{\alpha}{3\tau_s} \ln \mathcal{V} \right), \quad (4.11)$$

where $\tilde{\tau}_s$ and $\tilde{\tau}_b$ are given by:

$$\tilde{\tau}_s = \left(\frac{\lambda \xi}{2g_s^{3/2}} \right)^{2/3}, \quad (4.12)$$

$$\tilde{\tau}_b = \left(\frac{3|W_0|}{4|A|a} \sqrt{\tau_s} e^{a\tau_s} \right)^{2/3}. \quad (4.13)$$

These equations give the locus of the minimum as a perturbative expansion in α . As a check on the validity of these computations we also perform a numerical study of the minima of the potential for different values of α and compare the results with our analytical computation. The results are plotted in Fig. 1.

Figure 1: τ_b and τ_s at the minimum as functions of α . The dots are the analytical solutions while the crosses represent the numerical results.

We can see that for small values of α ($0 < \alpha < 3 \times 10^{-3}$) there is good agreement between the numerical location of the minimum coordinates and the approximate analytic solution.

Observation of Fig. 1 reveals that the deviation between the numerical and the analytical grows with α , but remains small (order of a few percent) throughout the range of values considered. The deviation between the analytical and the numerical results for τ_b is one order of magnitude larger than the one for τ_s - this is due to the exponential dependence of τ_b on τ_s as seen in Eq. (4.13), which amplifies the deviation.

As we consider larger values of α the linear approximation breaks down, as is illustrated in Fig. 2. In this regime the effect of the α'^3 also becomes negligible in the large volume limit. However, we see that the structure of the potential (in particular the minimum at exponentially large values of the volume) remains unaltered. This is quite striking and shows that these two terms can play a similar role in the stabilisation of the Kähler moduli of the theory.

Figure 2: $\tau_b(\alpha)$ and $\tau_s(\alpha)$: The linear expansion breaks down for higher values of α .

4.2 Redefining τ_b

We now consider the effects of redefining the large cycle τ_b . In this case the motivation for the redefinition is less strong as neither of the arguments presented in section 3 directly apply to this cycle. However it is still worth considering for completeness. We redefine the τ_b 4-cycle of $\mathbb{P}_{[1,1,1,6,9]}^4$ according to Eq. (3.1) and follow the same procedure as in the previous section. The Kähler potential becomes:

$$K = -2 \ln \left[\frac{1}{\lambda} ([\tau_b - \beta \ln(\mathcal{V})]^{3/2} - \tau_s^{3/2}) + \frac{\xi}{2} \left(\frac{S + \bar{S}}{2} \right)^{3/2} \right] + K_{cs}. \quad (4.14)$$

The scalar potential is given by

$$V = \frac{3|W_0|^2 \lambda^3 \xi}{4g_s^{3/2} \tau_b^{9/2}} + \frac{9|W_0|^2 \beta \lambda^2}{2\tau_b^4} + \frac{8a^2 |A|^2 \lambda^2 \sqrt{\tau_s} e^{-2a\tau_s}}{3\tau_b^{3/2}} - \frac{a\lambda^2 \tau_s e^{-2a\tau_s} (6\beta \ln \mathcal{V} + 3\beta + 2\tau_b) (A(\bar{A} + e^{a\tau_s} \bar{W}_0) + c.c.)}{\tau_b^4}, \quad (4.15)$$

which can be further simplified to

$$V = \frac{\Lambda}{\tau_b^{9/2}} + \frac{\Psi \beta}{\tau_b^4} + \Phi \frac{\sqrt{\tau_s} e^{-2a\tau_s}}{\tau_b^{3/2}} - \theta \frac{\tau_s e^{-a\tau_s}}{\tau_b^3} \left(1 + \frac{\beta}{\tau_b} (3 \ln \mathcal{V} + \frac{3}{2}) \right), \quad (4.16)$$

where

$$\Lambda = \frac{3|W_0|^2 \lambda^3 \xi}{4g_s^{3/2}}, \quad (4.17)$$

$$\Psi = \frac{9|W_0|^2 \lambda^2}{2}, \quad (4.18)$$

$$\Phi = \frac{8a^2 |A|^2 \lambda^2}{3}, \quad (4.19)$$

$$\theta = 2a\lambda^2 (A\bar{W}_0 + c.c.). \quad (4.20)$$

In this case the effect of the redefinition in Eq. (4.16) is to create a term that dominates in the LARGE volume limit over any other term in the potential (as it scales as $\sim \tau_b^{-4}$ while all other terms scale as $\sim \tau_b^{-9/2}$). In the limit of small β we find that the minimum of Eq. (4.16) is located at

$$\tau_s = \tilde{\tau}_s \left(1 + \frac{1}{3a\tau_s} + \frac{\beta}{\tau_b} \left(\frac{-44}{9} \ln \mathcal{V} + \frac{16}{9} \frac{\tau_b^{3/2}}{\tilde{\tau}_s^{3/2}} \right) \right), \quad (4.21)$$

$$\tau_b = \tilde{\tau}_b \left(1 - \frac{1}{2a\tau_s} + 2\beta \frac{a\tau_s}{\tau_b} \right), \quad (4.22)$$

where $\tilde{\tau}_s$ and $\tilde{\tau}_b$ are given by Eqs. (4.12) and (4.13) respectively.

In Fig. 3 we depict the numeric and analytic location of the minima as functions of β . The conclusions are essentially the same as for the previously studied case, the main difference being the fact that the allowed range for the loop factor β is much smaller.

Figure 3: τ_b and τ_s at the minimum as a function of β . The red dots are the analytical solution of Eqs. while the blue dots represent the numerical result.

In contrast to the case with τ_s , in this case the LARGE volume minimum does not survive for large values of β . This is because the correction to the scalar potential is dominant at large volumes over all other terms, and so gives a runaway behaviour. For sufficiently large β this runaway structure overwhelms all other features of the potential.

4.3 Summary

We have considered the effects of two possible field redefinitions on moduli stabilisation. In the better motivated case, that of the redefinition of τ_s , we find that the basic structure of the LARGE volume minimum is unaltered even though the effects of the redefinition dominate at large volume the α'^3 effects that played a crucial role in establishing the original LARGE volume minimum. For completeness we have also studied the case of the

redefinition of τ_b . In this case the redefinition gives a term in the scalar potential that at sufficiently large volume dominates all other terms and gives runaway.

5. Soft SUSY Breaking

Having studied the effects of field redefinitions on moduli stabilisation let us now see whether they can give any new effects in the study of supersymmetry breaking.

In the first formulation of the LARGE volume model it was originally assumed that the D7-brane supporting the MSSM fields and the D3-brane instanton wrap the same four-cycle, namely τ_s . However it was pointed out in [24] that instanton zero mode counting forbids this scenario. It was proposed in [25] that the simplest way to avoid this issue is to assume a threefold with at least three four-cycles: one large cycle and two small del Pezzo four-cycles. The volume of this class of Calabi-Yau can be written as

$$\mathcal{V} = (\eta_b \tau_b)^{3/2} - (\eta_s \tau_s)^{3/2} - (\eta_a \tau_a)^{3/2}, \quad (5.1)$$

where τ_b determines the volume of the Calabi-Yau, τ_s is wrapped by the D3-brane instanton and the four-cycle of size τ_a supports the MSSM D7 brane. Examples of explicit Calabi-Yaus with these structures can be found in [21, 22, 23]. Since $\mathbb{P}^4_{[1,1,1,6,9]}$ has only 2 Kähler moduli clearly it cannot be an example of a manifold obeying Eq. (5.1). Nonetheless, the conclusions in the previous section regarding moduli stabilisation will remain the same once we consider a geometrical setup obeying Eq. (5.1) as will be explained later.

Let us start by reviewing the computation of soft terms following the review [26]. This starts by performing an expansion of the Kähler potential and superpotential in powers of the matter fields :

$$W = \hat{W}(\Phi) + \mu(\Phi) H_1 H_2 + \frac{1}{6} Y_{\alpha\beta\gamma}(\Phi) C^\alpha C^\beta C^\gamma + \dots \quad (5.2)$$

$$K = \hat{K}(\Phi, \bar{\Phi}) + Z_{\alpha\bar{\beta}}(\Phi, \bar{\Phi}) C^\alpha C^{\bar{\beta}} + [Z(\Phi, \bar{\Phi}) H_1 H_2 + h.c.] + \dots \quad (5.3)$$

where Φ and C^α denote the moduli and the matter fields of the theory. In gravity mediation, the (scalar) soft SUSY breaking terms are found by expanding the $\mathcal{N} = 1$ scalar potential Eq. (2.5) in powers of the matter fields, using Eqs. (5.2) and (5.3). The SUSY breaking is controlled by the F-terms of the moduli fields of the theory

$$F^m = e^{\hat{K}/2} \hat{K}^{m\bar{n}} D_{\bar{n}} \bar{\hat{W}}. \quad (5.4)$$

From the fermionic part of the SUGRA Lagrangian we obtain the canonically normalised gaugino field $\hat{\lambda}^a = \text{Re}(f_a)^{1/2} \lambda^a$ and gaugino masses given by

$$M_{\hat{G}} = \frac{1}{2\text{Re}(f_i)} F^I \partial_I f_i. \quad (5.5)$$

The scalar Lagrangian can be written, for a diagonal matter metrics ($Z_{\alpha\bar{\beta}} = Z_\alpha \delta_{\alpha\bar{\beta}}$) as

$$\mathcal{L}_{soft} = \tilde{K}_\alpha \partial_\mu C^\alpha \partial^\mu \bar{C}^{\bar{\alpha}} - M_{\tilde{Q}_\alpha}^2 C^\alpha \bar{C}^{\bar{\alpha}} - \left(\frac{1}{6} A_{\alpha\beta\gamma} \hat{Y}_{\alpha\beta\gamma} C^\alpha C^\beta C^\gamma + B \hat{\mu} \hat{H}_1 \hat{H}_2 + h.c. \right), \quad (5.6)$$

where the scalar masses and A-terms are given by

$$M_Q^2 = M_{3/2} + V_0 - F^I F^{\bar{J}} \partial_I \partial_{\bar{J}} \ln Z_\alpha, \quad (5.7)$$

$$A_{\alpha\beta\gamma} = F^I \partial_I K + F^I \partial_I Y_{\alpha\beta\gamma} - F^I \partial_I \ln(Z_\alpha Z_\beta Z_\gamma). \quad (5.8)$$

Note that due to Peccei-Quinn shift-symmetry of the Kähler moduli, these fields are forbidden to appear in the holomorphic superpotential. The superpotential Yukawa couplings, $Y_{\alpha\beta\gamma}$, can therefore only depend on complex structure moduli. Since flux stabilisation ensures that complex structure moduli do not break SUSY (or at least the effects are highly suppressed), the second term in Eq. (5.8) vanishes.

The μ term is

$$\hat{\mu} = \left(e^{K/2} + M_{3/2} Z - \bar{F}^{\bar{I}} \partial_{\bar{I}} Z \right) (Z_{H_1} Z_{H_2})^{-1/2}. \quad (5.9)$$

Finally the $B\mu$ -term is given by

$$\begin{aligned} B\hat{\mu} = & \frac{1}{\sqrt{Z_{H_1} Z_{H_2}}} \left(e^{K/2} \mu (F^I \partial_I K + F^I \partial_I \ln \mu - F^I \partial_I \ln(Z_{H_1} Z_{H_2}) - M_{3/2}) \right. \\ & + (2M_{3/2}^2 + V_0) Z - M_{3/2} \bar{F}^{\bar{I}} \partial_{\bar{I}} + M_{3/2} F^I (\partial_I Z - Z \partial_I \ln(Z_{H_1} Z_{H_2})) \\ & \left. - F^I F^{\bar{J}} (\partial_{\bar{I}} \partial_{\bar{J}} Z - (\partial_{\bar{I}} Z) \partial_{\bar{J}} \ln(Z_{H_1} Z_{H_2})) \right). \end{aligned} \quad (5.10)$$

In order to compute these soft SUSY breaking terms one must specify the Kähler potential and superpotential for moduli fields $\hat{K}(\Phi, \bar{\Phi})$ and $\hat{W}(\Phi)$ in Eqs. (5.2) and (5.3) as well as the gauge kinetic function f_i and the matter metrics, $Z(\Phi)$. It is therefore crucial to note that there are two regimes in the effective field theory: the geometric regime and the singular cycle regime [25]. Our purpose here is to see whether moduli redefinitions can affect the results on supersymmetry breaking that were found in [25].¹

In the geometric regime all the four-cycles are larger than the string scale. In this regime the effective field theory is determined by:

$$\hat{K}(\Phi, \bar{\Phi}) = -2 \ln \left(\mathcal{V} + \frac{\hat{\xi}}{2} \right) - \ln(S + \bar{S}) + K_{CS}, \quad (5.11)$$

$$\hat{W}(\Phi) = W_0 + A e^{-a T_s}, \quad (5.12)$$

$$f_i = T_a - \frac{1}{2} \kappa_i S. \quad (5.13)$$

where the volume is given by Eq. (5.1) and the matter metric is

$$Z = \frac{\tau_a^q f(\Phi)}{\tau_b^p}, \quad (5.14)$$

¹In [25] there is a cancellation of anomaly-induced soft terms that comes from the no-scale structure. This cancellation came from using conventional formulae for anomaly-mediated mass terms. It has recently been argued in [29] that these formulae are not correct, and if this is the case then the cancellation used in [25] will not apply. We note this issue but a detailed discussion of the form of anomaly-mediated soft terms is beyond the scope of this paper.

with $f(\Phi)$ being a function of the complex structure moduli. The form of the modular dependence of (5.19) comes from taking the leading powers of the moduli. Values of p and q can be either deduced or significantly constrained by examining the behaviour of the physical Yukawa couplings under rescaling of the several moduli in the theory, as described in [27]. Arguing that in local models the interactions should be independent of the overall volume it is found that $p_\alpha = 1, \forall \alpha$. The q is more delicate and can depend on whether a field originates from ‘internal’ or ‘normal’ modes of branes [28]. In what follows we leave p and q unspecified. This allows one to find more generic expressions for the soft terms and makes clear the nature of the cancellation of the leading order contributions.

In the singular cycle regime, the MSSM four-cycle is much smaller than the string scale. In this regime the theory is determined by:

$$\hat{K}(\Phi, \bar{\Phi}) = -2 \ln \left(\mathcal{V} + \frac{\hat{\xi}}{2} \right) + c \frac{\tau_a^2}{\mathcal{V}} - \ln(S + \bar{S}) \quad (5.15)$$

$$\hat{W}(\Phi) = W_0 + A e^{-a T_s} \quad (5.16)$$

$$f_i = s_{ik} T_k + \delta_i S \quad (5.17)$$

where the volume is given by

$$\mathcal{V} = (\eta_b \tau_b)^{3/2} - (\eta_s \tau_s)^{3/2} \quad (5.18)$$

and the matter metric is

$$Z = \frac{g(\Phi) + \tau_a^q h(\Phi)}{\tau_b^p}, \quad (5.19)$$

with c being a constant and $g(\Phi)$ and $h(\Phi)$ being arbitrary functions of the complex structure moduli/dilation. The quadratic term in τ_s in Eq. (5.15) is introduced to ensure that the τ_s kinetic term is well defined when $\tau_s = 0$.

5.1 Redefinition of T_a modulus and implications for soft SUSY breaking terms

Our aim is to investigate the effects of the T_a modulus redefinition in the scale of the soft SUSY breaking terms. In particular one seeks to compare the resulting terms to the ones found for the same geometrical configuration in [25]. One might also consider redefining the remaining Kähler moduli of the theory, but the effects will be subleading. We therefore neglect them and concentrate on the redefinition of T_a only.

A fully consistent analysis must investigate the effects of the T_a redefinition in the Kähler potential for moduli and in the matter metrics. We will proceed by steps, analysing first the case where we redefine T_a in the Kähler potential only and then studying the full case.

5.1.1 Redefining T_a in the Kähler potential

First we investigate the consequences of applying the redefinition in Eq. (3.1) to the Kähler potential for moduli fields, $\hat{K}(\Phi, \bar{\Phi})$. As the Standard Model cycle is taken to be stabilised

by a D-term we must impose the following condition for the Kähler modulus T_a :

$$\partial_a K = 0 \Leftrightarrow \tau_a = \alpha \ln \mathcal{V}. \quad (5.20)$$

From this condition and since the superpotential is independent of T_a , it follows that $F_a = 0$. In [25] the vanishing of F_a led to the vanishing of F^a . However since the Kähler metric is non diagonal and $\tau_a \neq 0$ here we find

$$\begin{aligned} F^a &= K^{a\bar{b}} F_{\bar{b}} + K^{a\bar{s}} F_{\bar{s}} \\ &= -3\alpha M_{3/2}. \end{aligned} \quad (5.21)$$

This is a significant difference from [25]. For the computation of the soft terms one also needs the F-terms for the remaining Kähler moduli. These are found to be

$$F^b = -2M_{3/2}\tau_b, \quad (5.22)$$

$$F^s = -2M_{3/2}\tau_s, \quad (5.23)$$

at leading order in the volume expansion. We note that even though the τ_a dependence of $\hat{K}(\Phi, \bar{\Phi})$ is different in the geometric and singular cycle regimes, the results in Eqs. (5.21)-(5.23) hold in both regimes.

In the computation of the soft SUSY breaking terms we will neglect the α'^3 contributions to the Kähler potential as well as the nonperturbative superpotential. This is because the SUSY breaking structure of the LARGE volume models is essentially inherited from no-scale, and the contributions of the α' corrections to the soft terms is volume suppressed compared to the terms we will consider.

Geometric Regime

Redefining the τ_a in the Kähler potential, Eq. (5.11), we find the soft terms to be given by:

$$M_{\tilde{G}} = \frac{-3}{2} \alpha \frac{M_{3/2}}{\text{Re}(f_i)}, \quad (5.24)$$

$$M_{\tilde{Q}}^2 = M_{3/2}^2(1-p) + \frac{9q}{4} \frac{M_{3/2}^2}{\ln^2 \mathcal{V}}, \quad (5.25)$$

$$\hat{\mu} = \frac{Z}{\sqrt{Z_{H_1} Z_{H_2}}} M_{3/2} \left((1-p + \frac{3}{2} \frac{q}{\ln \mathcal{V}}) \right), \quad (5.26)$$

where we have set the superpotential μ term to vanish.

The $B\hat{\mu}$ term is given in this regime by

$$\begin{aligned} B\hat{\mu} &= \frac{M_{3/2}^2 Z}{\sqrt{Z_{H_1} Z_{H_2}}} \left((2 - 2p - p(p+1) + 2p^2) + \frac{1}{\ln \mathcal{V}} 3(1-p)(q_{H_1} + q_{H_2}) + \right. \\ &\quad \left. \frac{1}{\ln^2 \mathcal{V}} \frac{9q}{2} (q_{H_1} + q_{H_2} - \frac{q-1}{2}) \right) \end{aligned} \quad (5.27)$$

where we have assumed that $\mu = 0$ and that all the fields feel the overall volume of the CY in the same way, i.e., $p = p_{H_1} = p_{H_2}$.

The A-term in the geometric regime is given by

$$A_{\alpha\beta\gamma} = M_{3/2}(3 - 3p) - 3M_{3/2}\frac{\tau_s^{3/2}}{\mathcal{V}} + \frac{3M_{3/2}}{2\ln\mathcal{V}}(q_\alpha + q_\beta + q_\gamma). \quad (5.28)$$

Following the rescaling arguments in [27], we set $p = 1$ and note that the leading order terms cancel in all soft terms, leaving only the volume suppressed contributions.

Neglecting $\mathcal{O}(1)$ factors we summarise the results in the following table

Soft-term	Scale
$M_{\tilde{G}}$	$M_{3/2}$
$M_{\tilde{Q}}^2$	$M_{3/2}^2/\ln^2\mathcal{V}$
$\hat{\mu}$ -term	$M_{3/2}\ln\mathcal{V}$
$B\hat{\mu}$ -term	$M_{3/2}^2/\ln^2\mathcal{V}$
A-term	$M_{3/2}\ln\mathcal{V}$

Singular Cycle Regime

We now compute the soft terms in the singular cycle regime. We start by defining

$$\Gamma \equiv \frac{h(\Phi)\tau_a^q}{g(\Phi) + h(\Phi)\tau_a^q}, \quad (5.29)$$

then the soft terms are:

$$M_{\tilde{Q}}^2 = M_{3/2}^2(1 - p) + \frac{M_{3/2}^2}{\ln^2\mathcal{V}}\frac{9q}{4}\Gamma(q - 1 - q\Gamma), \quad (5.30)$$

$$\hat{\mu} = \left(e^{K/2}\mu + M_{3/2}Z(1 - p) + \frac{3q}{2}\frac{M_{3/2}}{\ln\mathcal{V}}\Gamma \right) \frac{1}{\sqrt{Z_{H_1}Z_{H_2}}}, \quad (5.31)$$

$$\begin{aligned} B\hat{\mu} = & \frac{M_{3/2}^2}{\sqrt{Z_{H_1}Z_{H_2}}} \left(Z(2 - 2p - p(p + 1) + p(p + 1)) + \frac{1 - p}{\ln\mathcal{V}} \left(\frac{3}{2}Z\Psi + 3pq\frac{\tau_a^q h(\Phi)}{\tau_b^p} \right) + \right. \\ & \left. \frac{9q/4}{\ln\mathcal{V}} \frac{\tau_a^q h(\Phi)}{\tau_b^p} (\Psi - q - 1) \right), \end{aligned} \quad (5.32)$$

$$A_{\alpha\beta\gamma} = M_{3/2}(3 - p_\alpha - p_\beta - p_\gamma) - 3M_{3/2}\frac{\tau_s^{3/2}}{\mathcal{V}} + \frac{3M_{3/2}}{2\ln\mathcal{V}} \sum_{\xi=\alpha,\beta,\gamma} q_\xi \Gamma_\xi, \quad (5.33)$$

where

$$\Psi \equiv \frac{q_1 h_1(\Phi)\tau_a^{q_1}}{g_1 + h_1(\Phi)\tau_a^{q_1}} + \frac{q_2 h_2(\Phi)\tau_a^{q_2}}{g_2 + h_2(\Phi)\tau_a^{q_2}}.$$

In the singular cycle regime the rescaling arguments used to find the modular dependence of the matter metric no longer apply. Nonetheless locality implies that $p = 1$, then the leading order contributions to the soft terms vanish and the result found in this regime mirror the ones of the geometric regime up to factors of $\Gamma \approx \mathcal{O}(1)$.

The significance of this is that soft terms are of a similar order to the gravitino mass, in contrast to the behaviour in [25] where soft terms were significantly suppressed compared to the gravitino mass.

5.1.2 Redefining T_a in the matter metrics

In this section we study the effects on the scale of the soft terms of the MSSM four-cycle redefinition in the matter metrics. Once we take the redefinition of τ_a into account, the geometric regime matter metric becomes

$$Z = \frac{(\tau_a - \alpha \ln \mathcal{V})^q f(\Phi)}{\tau_b^p}, \quad (5.34)$$

while in the singular cycle regime we should have

$$Z = \frac{g(\Phi) + (\tau_a - \alpha \ln \mathcal{V})^q h(\Phi)}{\tau_b^p}. \quad (5.35)$$

It is crucial to note that, in general, the metrics in Eqs. (5.34) and (5.35) are singular and/or have singular derivatives once we impose the vanishing D-term condition. This poses a problem for the computation of soft SUSY breaking terms. A way to avoid this singular behaviour is to argue that the Kähler potential will receive higher order α' corrections which will modify the vanishing D-term condition. We sketch this idea in the geometric regime of the effective field theory and argue that the same argument holds in the singular cycle regime. Let $\phi(T_i)$ denote an arbitrary function of the Kähler moduli of the theory, then the full moduli Kähler potential for the $\mathcal{N} = 1$ SUGRA in the geometric regime can be written as

$$\hat{K}(\Phi, \bar{\Phi}) = -2 \ln \left(\mathcal{V} + \frac{\hat{\xi}}{2} + \phi(T_i) \right) - \ln(S + \bar{S}) + K_{CS}, \quad (5.36)$$

where we expect $\phi(T_i) \ll \mathcal{V}$. Then the vanishing D-term condition becomes

$$\partial_a \hat{K} = 0 \Leftrightarrow \frac{\partial}{\partial \tau_a} (\mathcal{V} + \phi(T_i)) = 0. \quad (5.37)$$

After redefining τ_a in the volume this yields

$$\sqrt{\tau_a - \alpha \ln \mathcal{V}} \left(1 + \frac{3}{2} \frac{\alpha \sqrt{\tau_a}}{\mathcal{V}} \right) = -\frac{2}{3} \frac{\partial}{\partial \tau_a} \phi(T_i). \quad (5.38)$$

Since we do not know the explicit form of $\phi(T_i)$ we cannot solve Eq. (5.38). Nonetheless one may write the solution as

$$\tau_a = \alpha \ln \mathcal{V} + \theta, \quad (5.39)$$

where $\theta \ll \alpha \ln \mathcal{V}$ is a function of the moduli of the theory, related to $\phi(T_i)$ by

$$\sqrt{\theta} \approx -\frac{2}{3} \frac{\partial}{\partial \tau_a} \phi(T_i). \quad (5.40)$$

Once these higher order corrections are taken into account, Eqs. (5.34) and (5.35) no longer have a singular behaviour and the soft terms will be given as functions of θ .

One must also point out that a full treatment of the problem does not involve a redefinition of τ_a in the gauge kinetic functions, Eqs. (5.13) and (5.17), since these are protected by holomorphy. As a consequence of this, gaugino masses in the geometric and singular cycle regimes will still be given by Eqs. (5.24)-(5.30) respectively in the full case.

Geometric Regime

Proceeding in the same way as before we compute the leading order contributions in the volume expansion of the soft terms:

$$M_Q^2 = M_{3/2}^2 \left(1 - p - q_\alpha \frac{3\alpha}{2\theta} + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.41)$$

$$\hat{\mu} = \frac{M_{3/2} Z}{\sqrt{Z_{H1} Z_{H2}}} \left(1 - p + \frac{3}{2} \frac{\alpha q_\alpha}{\theta} + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.42)$$

$$B\hat{\mu} = \frac{Z}{\sqrt{Z_{H1} Z_{H2}}} M_{3/2}^2 \left((p^2 - 3p + 2) - \frac{3}{2} \frac{\alpha}{\theta} q_\alpha + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.43)$$

$$A_{\alpha\beta\gamma} = 3M_{3/2} \left(1 - p + \frac{1}{\mathcal{V}} \left(\theta^{3/2} + \frac{3}{4} \sqrt{\tau_a} \frac{\alpha^2}{\theta} (q_\alpha + q_\beta + q_\gamma) \right) + \mathcal{O}(\mathcal{V}^{-2}) \right). \quad (5.44)$$

Singular Cycle Regime

The soft terms in the singular cycle regime, once we redefine τ_a in the matter metric become:

$$M_Q^2 = M_{3/2}^2 \left(1 - p - q_\alpha \frac{3\alpha}{2\theta} \tilde{\Gamma} + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.45)$$

$$\hat{\mu} = \frac{M_{3/2} Z}{\sqrt{Z_{H1} Z_{H2}}} \left(1 - p + \frac{3}{2} \frac{\alpha q_\alpha}{\theta} \tilde{\Gamma} + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.46)$$

$$B\hat{\mu} = \frac{Z}{\sqrt{Z_{H1} Z_{H2}}} M_{3/2}^2 \left((p^2 - 3p + 2) - \frac{3}{2} \frac{\alpha}{\theta} q_\alpha \tilde{\Gamma} + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.47)$$

$$A_{\alpha\beta\gamma} = 3M_{3/2} \left(1 - p + \frac{3}{4\mathcal{V}} \alpha^2 \frac{\sqrt{\tau_a}}{\theta} \sum_{\xi=\alpha,\beta,\gamma} q_\xi \tilde{\Gamma}_\xi + \frac{c\theta^2}{2\mathcal{V}} + \mathcal{O}(\mathcal{V}^{-1}) \right), \quad (5.48)$$

where $\tilde{\Gamma}_\alpha$ is defined as

$$\tilde{\Gamma}_\alpha \equiv \frac{h(\Phi)\theta^q}{g(\Phi) + h(\Phi)\theta^q}. \quad (5.49)$$

Even though an analysis with generic modular dependence in the matter metrics requires one to consider higher order α' corrections to the Kähler potential into account, there is a particular value of q for which this is not strictly necessary. If one sets $q = 2$ in the singular cycle regime, the matter metrics and its derivatives are well defined even if we set $\theta \rightarrow 0$. In this particular case we find, after setting $p = 1$:

$$\hat{\mu} = 0 = A_{\alpha\beta\gamma}, \quad (5.50)$$

$$M_Q^2 \propto \frac{\ln \mathcal{V}}{\mathcal{V}^3} \alpha^5, \quad (5.51)$$

$$B\hat{\mu} \propto \frac{\alpha^5 \ln \mathcal{V}}{\mathcal{V}^2}. \quad (5.52)$$

In this case one also finds that the cancellation of the leading order terms happens as before, leaving only highly volume suppressed terms. The contribution to the soft terms computed in [25] will then dominate over the ones considered here.

Going back to the generic case, one must note that in both regimes, the usual cancellation of leading order terms is present if $p = 1$. The scale of the soft terms is then parametrised by the ratio $\frac{\alpha}{\theta}$, where θ is essentially a derivative of the higher order α' terms in the Kähler potential for moduli fields, $\phi(T_i)$.

A full computation of the soft terms must include at least the terms in Eqs. (5.41)-(5.48) and the ones computed in [25]. To understand the relative size of both contributions and the scale of resulting the soft terms it is necessary to know $\phi(T_i)$ explicitly. At the moment this is beyond our possibilities. Nonetheless it is interesting to point out that it might be possible that the scale of the soft terms is set by the subleading terms in the Kähler potential. The main point here is to note that if we redefine the MSSM four-cycle according to Eq. (3.1) the theory is still well behaved and we can get non vanishing soft terms.

6. Conclusions

In this paper we have studied the effects of one-loop moduli redefinitions on moduli stabilisation in the LARGE volume scenario. We have reviewed the origins of such redefinitions in orbifold models and also given a new argument for the existence of such redefinitions in the geometric regime. In our study of the effects on moduli stabilisation we have assumed that the form of the Kähler potential is only altered by re-expressing the geometric volume in terms of the redefined moduli variables. This leaves one obvious direction for future work as it would be very interesting to find loop-corrected expressions for the Kähler potential including blow-up modes (the results of [4] apply only to the overall volume modulus).

We found that redefinitions of the small moduli do not alter the basic structure of the LARGE volume minimum: the minimum remains in qualitatively the same location and at exponentially large volume. This is actually quite striking as the redefinition generates terms that in the scalar potential at large volumes dominate the α'^3 corrections. For redefinitions of the overall volume, which is less motivated, the modified Kähler potential gives a scalar potential that actually leads to runaway and removes the LARGE volume minimum.

We also studied the possible effects of moduli redefinitions on supersymmetry breaking. There we found that redefinitions may have the ability to modify the results of [25] and induce soft terms of a similar order to the gravitino mass. However there were certain ambiguities which depend on the form of the matter metrics, and resolving these ambiguities depends on corrections to the Kähler potential. While the results of this section may be potentially interesting, what is really needed is a full CFT computation to see the effect of redefinitions on terms in the Kähler potential, which is however beyond the scope of this work.

We thank Shanta de Alwis, Marcus Berg, Michael Haack, Eran Palti and Fernando Quevedo for useful discussions. JC is supported by a Royal Society University Research Fellowship and by Balliol College, Oxford. FGP is supported by Fundação para a Ciência e a Tecnologia (Portugal) through the grant SFRH/BD/35756/2007.
